Practical Lab: Exploring Virtualization & Emulation

This guide will walk you through different forms of virtualization, from lightweight emulation to full-blown server management. You will use **VirtualBox** (for Windows/macOS) or **QEMU** (for Linux) as your primary tool.

Part 1: Host Setup - Your Virtualization Tool

First, install the correct tool for your operating system.

For Windows & macOS Hosts: VirtualBox

1. **Download & Install:**
   - Go to the VirtualBox downloads page and download the installer for your OS.
   - Also, download the **VirtualBox Extension Pack** from the same page.
   - Run the main installer, accepting the defaults. On macOS, you must **Allow** the Oracle system extension in `System Settings > Privacy & Security`.
   - Double-click the downloaded Extension Pack file to install it.
2. **How to Use VirtualBox:**
   - You'll use the graphical interface to create and manage VMs.
   - Click **"New"** to start a wizard for a new VM.
   - Modify settings by selecting a VM and clicking **"Settings"**.

For Linux Hosts: QEMU

1. **Download & Install:**
   - QEMU and KVM (for hardware acceleration) are in most standard repositories. On Debian/Ubuntu, open a terminal and run:
     ```
     $ sudo apt update
     $ sudo apt install qemu-system-x86 qemu-system-i386 bridge-utils
     ```
   - Add your user to the `kvm` group to run VMs without `sudo`. You must log out and back in for this to take effect.
     ```
     $ sudo usermod -a -G kvm $USER
     ```
2. **How to Use QEMU:**
   - QEMU is command-line driven. You'll create disks with `qemu-img` and launch VMs with `qemu-system-x86_64`.
   - A typical launch command looks like this, with flags specifying resources:
     ```
     $ qemu-system-x86_64 -m 1G -hda disk_image.qcow2 -cdrom installer.iso
     ```

Part 2: Lightweight *Emulation* with FreeDOS 🕹️

Here, we'll explore a simple, non-multitasking OS to understand basic machine emulation.

1. **Download Resources:**
   - Download the **FreeDOS 1.3 Live CD** from the official site. You'll need the `FD14-LiveCD.zip` file. Unzip it to get the `.iso` file.
   - Download a classic shareware DOS game, like the first episode of **DOOM** (`doom19s.zip`), from a trusted archive. Unzip it into a folder named `doom`.
2. **Create the FreeDOS VM:**
   - **VirtualBox:**
     1. Click **"New"**. Name: `FreeDOS`, Type: `Other`, Version: `DOS`.
     2. Memory: `64 MB`.
     3. Hard Disk: Create a new VDI, `128 MB`, fixed size.
     4. In **Settings > Storage**, select the empty CD drive, click the CD icon on the right, and **Choose a disk file...** to select your `FD14LIVE.iso`.
   - **QEMU:**
     1. Create a 128M hard disk image.
        ```
        $ qemu-img create -f qcow2 freedos.qcow2 500M
        ```
     2. Launch the VM with the Live CD.
        ```
        $ qemu-system-i386 -machine accel=kvm:tcg -m 128 -cpu host \
        -k pt-pt -rtc base=localtime -device adlib -device sb16 \
        -device cirrus-vga -display gtk -hda $DISK \
        -cdrom /tmp/freedos/FD14LIVE.iso -boot d
        ```
3. **Install and Set Up FreeDOS:**
   - Boot the VM and select "Install to harddisk".
   - Follow the on-screen prompts. It will ask to partition and format the drive (`C:`). Proceed with the default options.
   - Once installation is complete, shut down the VM. In VirtualBox, remove the ISO from the virtual CD drive. In QEMU, remove the `-cdrom` and `-boot d` flags for the next launch.
4. **Get The Game into the VM:** We will create a second CD image containing the game.
   - **On Linux:** Qemu can make a FAT drive from a folder.
   - **On Windows/macOS:** Use a free tool like AnyBurn to "Create ISO from files/folders".
   - **Attach the game ISO:**
     - **VirtualBox:** Go to **Settings > Storage**. Click the "Add Optical Drive" icon on the IDE Controller, then add your `doom.iso`.
     - **QEMU:** Add a second drive to your launch command: `-drive file=fat:rw:/tmp/games/doom,form`
   - **Start FreeDOS.** Your game CD will likely appear as the `D:` drive. Type `D:` to switch to it, then run `INSTALL.BAT` or the game's `.EXE` file.
5. **Play the Game**

Part 3: Lightweight Virtualization with Alpine Linux Alpine 🏔️

Let's install a modern, minimal Linux distribution that is the foundation for many containers.

1. **Download Alpine:**
   - Go to the Alpine Linux downloads page and get the **STANDARD** version for your architecture (usually either x86_64 or aarch64 ISO).
2. **Install Alpine:**
   - **VirtualBox:**
     1. Create a new VM. Name: `Alpine`, Type: `Linux`, Version: `Linux 2.6 / 3.x / 4.x (64-bit)`.
     2. Memory: `1G`. Hard Disk: `8 GB`.
     3. Attach the Alpine ISO in **Settings > Storage**.
   - **QEMU:**
     ```
     $ qemu-img create -f qcow2 alpine.qcow2 8G
     $ qemu-system-x86_64 -m 1G -hda alpine.qcow2 -cdrom path/to/alpine.iso -boot d
     ```

- Boot the VM and log in as `root` (no password). Run `setup-alpine` and follow the prompts. A "sys" install to `sda` is a good choice. When done, reboot and detach the ISO.

3. **Explore Network Types:**
   - **NAT (Default):** With the default network setting, start the VM and check its IP address.

     ```
     # Inside Alpine VM
     $ ip addr show
     ```

     You will see an IP like `10.0.2.15`. You can reach the internet (e.g., `ping google.com`), but you can't easily reach the VM from your host.
   - **Bridge:** Shut down the VM.
     - **VirtualBox:** Go to **Settings > Network**. Change **Attached to:** from `NAT` to `Bridged Adapter`.
     - **QEMU:** Modify your launch command to use a bridge. This is more complex and system-dependent. Here is a sample code:

     ```
     echo -e "Setup Bridge Interface"
     sudo /sbin/ip link add virtbr0 type bridge
     sudo /sbin/ip link set dev $INTERFACE master virtbr0
     sudo /sbin/ip addr flush dev $INTERFACE
     sudo /sbin/dhclient virtbr0
     sudo /sbin/ip link set dev $INTERFACE up
     sudo /sbin/ip link set dev virtbr0 up

     echo -e "Start Alpine (BRIDGE)"
     sudo qemu-system-x86_64 -machine accel=kvm:tcg -m 4G -smp 4 -cpu host \
     -k pt-pt -rtc base=localtime -display gtk -hda $DISK \
     -netdev bridge,id=net0,br=virtbr0 -device virtio-net-pci,netdev=net0

     echo -e "Clean Bridge Interface"
     sudo /sbin/ip link set virtbr0 down
     sudo /sbin/ip link del virtbr0
     sudo /sbin/dhclient $INTERFACE
     ```

   - Start the VM again and run `ip addr show`. You should now see an IP address from your local home network (e.g., `192.168.1.123`).

4. **Set Up a Web Server:**
   - Alpine uses `busybox httpd`. Install the package for extra features.

     ```
     # Inside Alpine VM
     $ doas apk add busybox-extras
     ```

   - Create a directory for your web page.

     ```
     $ doas mkdir -p /var/www/localhost/htdocs
     ```

   - Create a simple HTML page.

     ```
     $ echo '<h1>Hello from Alpine Linux!</h1>' > /var/www/localhost/htdocs/index.html
     ```

   - Start the web server.

     ```
     $ doas httpd -f -p 80 -h /var/www/localhost/htdocs
     ```

   - From your **host machine's web browser**, navigate to the Alpine VM's IP address. You should see your message!

Part 4: Server Management with Proxmox VE 🖥️

Let's virtualize the virtualizer! We will install Proxmox, a bare-metal hypervisor, inside a VM.

⚠️ **CAUTION: Nested Virtualization** You are about to run a hypervisor (Proxmox) inside another hypervisor (VirtualBox/QEMU). This is called **nested virtualization**. It is very demanding on your CPU and will be slow. This exercise is for demonstration purposes only.

1. **Download Proxmox:**
   - Go to the Proxmox VE downloads page and get the latest ISO Installer.
2. **Create the Proxmox VM:** This VM needs more resources.
   - **VirtualBox:**
     1. Create a VM. Name: `Proxmox`, Type: `Linux`, Version: `Debian (64-bit)`.
     2. Memory: `4096 MB` or more. Processors: 2 or more.
     3. Hard Disk: `32 GB` or more.
     4. In **Settings > System > Processor**, check **Enable Nested VT-x/AMD-V**.
     5. In **Settings > Network**, set it to **NAT**.
     6. Configure port forwarding to redirect Host port 8006 to Guest port 8006.
     7. Attach the Proxmox ISO.
   - **QEMU:**

```
$ qemu-img create -f qcow2 proxmox.qcow2 32G
# The '-cpu host' flag is critical for passing through virtualization capabilitie
$ qemu-system-x86_64 -m 4096 -smp 2 -cpu host -hda proxmox.qcow2 -cdrom proxmox.i
```

3. **Install and Configure:**
   - Boot the VM and follow the Proxmox installation steps. It's a standard graphical installer.
   - For networking, provide a static IP on your home network (e.g., `192.168.1.200`).
   - After installation, reboot and detach the ISO.
4. **Access the Web Portal:**
   - On the Proxmox console, it will display the URL to access. From your **host machine's web browser**, navigate to `https://localhost:8006`.
   - You will see a security warning about the certificate; it's safe to proceed.
   - Log in with `root` and the password you set during installation.
5. **Launch a Guest VM in Proxmox:**
   - Inside the Proxmox web portal, you can now create a new VM or container.
   - Challenge: Try to create a new **Alpine Linux VM** inside Proxmox by uploading the Alpine ISO to the Proxmox server and following the web interface prompts.

Part 5: Bonus Exercise - Emulating Android OS 🤖

The best way to emulate Android is using the official tools from Google.

1. **Download & Install Android Studio:**
   - Go to the Android Studio download page and get the installer for your OS.
   - The installation process is a standard wizard. It will download many components, so it will take time.
2. **Use the AVD Manager:**
   - Open Android Studio. You don't need to create a project.
   - From the welcome screen or the **Tools** menu, select **AVD Manager** (Android Virtual Device Manager).
3. **Create a Virtual Device:**
   - Click **"Create Virtual Device..."**.
   - Choose a phone hardware profile (e.g., Pixel 7).
   - Select a system image (a version of Android) to download.
   - Give your AVD a name and click **Finish**.
4. **Launch the Emulator:**

- Back in the AVD Manager, click the “Play” icon next to your new virtual device.
- A new window will open, booting a full, emulated Android operating system. Explore the interface, open apps, and use the browser, just like a real phone.
